28 **Abstract.**

29 The spaceborne Advanced Very High Resolution Radiometer (AVHRR) sensor data record is  
30 approaching 40 years, providing a crucial asset for studying long-term trends of aerosol  
31 properties regionally and globally. However, due to limitations of its channels' information  
32 content, aerosol optical depth (AOD) data from AVHRR over land are still largely lacking. In  
33 this paper, we describe a new physics-based algorithm to retrieve aerosol loading over both land  
34 and ocean from AVHRR for the first time. The over-land algorithm is an extension of our Sea-  
35 viewing Wide Field-of-view Sensor (SeaWiFS) and Moderate Resolution Imaging  
36 Spectroradiometer (MODIS) Deep Blue algorithm, while a simplified version of our Satellite  
37 Ocean Aerosol Retrieval (SOAR) algorithm is used over ocean. We compare retrieved AVHRR  
38 AOD with that from MODIS on a daily and seasonal basis, and find in general good agreement  
39 between the two. For the satellites with equatorial crossing times within two hours of solar noon,  
40 the spatial coverage of the AVHRR aerosol product is comparable to that of MODIS, except over  
41 very bright arid regions (such as the Sahara), where the underlying surface reflectance at 630 nm  
42 reaches the critical surface reflectance. Based upon comparisons of the AVHRR AOD against  
43 Aerosol Robotic Network (AERONET) data, preliminary results indicate that the expected error  
44 confidence interval envelope is around  $\pm(0.03+15\%)$  over ocean and  $\pm(0.05+25\%)$  over land for  
45 this first version of the AVHRR aerosol products. Consequently, these new AVHRR aerosol  
46 products can contribute important building blocks for constructing a consistent long-term data  
47 record for climate studies.

48

49 1. Introduction

50  
51 Success in the quest of quantifying anthropogenic impacts on global change accurately  
52 requires decades-long observations of atmospheric, oceanic, and land imaging from space.  
53 Analyses of the longest (nearly 40-year) daily record of imager data acquired by the Advanced  
54 Very High Resolution Radiometer (AVHRR) aboard the National Oceanic and Atmospheric  
55 Administration (NOAA) polar-orbiting meteorological satellites can contribute important  
56 building blocks toward this quest. The unique series of AVHRR measurements can be obtained  
57 from NOAA-7 (launched in 1981) to NOAA-19 (launched in 2009), comprised of data mainly  
58 from two different sensors: the AVHRR/2 instrument that spans from July 1981 to November  
59 2000, followed by the AVHRR/3 to the present. To retrieve aerosol properties from both natural  
60 and anthropogenic sources, over both land and ocean, we need to first examine the mechanical,  
61 optical, and radiometric characteristics of the AVHRR sensors. These are discussed below.

62 AVHRR scans mechanically with  $\pm 55^\circ$  from nadir and covers a swath width of 2,800 km.  
63 Although the native spatial resolution in local area coverage (LAC) mode is 1.1 km at the sub-  
64 satellite point, the actual pixel size and shape are somewhat dependent on scan angle. The LAC  
65 data are resampled at  $\sim 4$  km spatial resolution to give a global area coverage (GAC) data set.  
66 Within each block of three across-track scan lines by five pixels along-track of LAC pixels, the  
67 first four pixels in the first scan line are averaged and the other eleven pixels are skipped. Thus,  
68 the AVHRR GAC data are a 4/15 partial sampling of every three by five pixel block, and fifteen  
69 being close to the square of four, are often referred to as '4 km' data. The GAC record for a 24-  
70 hour period (day and night) totals 0.6 GB, a large volume in the late 1970s but trivial today  
71 (Kidwell, 1997).

72 To fuel the mechanical complexity further, those satellites from NOAA-7 in July 1981 to  
73 NOAA-14 in 2000 were permitted to drift in orbit, where the drift or precession was two to three  
74 minutes per month in terms of later equatorial crossing times, in turn, introducing artifacts in  
75 AVHRR data (Kaufman et al., 2000; Tucker et al., 2005). Our previous results also indicate that  
76 this orbital drift imposes significant challenges in determining trends of aerosol loading over  
77 land and ocean due to changes in sampling spatial coverage with time (Hsu et al., 2012). Orbital  
78 drift was greatly minimized after the launch of NOAA-16 in 2000, and the viewing geometry  
79 information for these later sensors is provided within the Level 1 (L1B) input files. Thus, for  
80 processing the pre-NOAA K/L/M (or prior to NOAA-15) AVHRR data, we need to calculate the  
81 sun-target-sensor geometries directly from the orbital elements of the satellites. The orbital  
82 elements, including eccentricity, semi-major axis, inclination, location of ascending node,  
83 argument of periapsis, and the anomaly, are obtained from the Two-Line-Elements satellite  
84 attitude data source provided by the North American Aerospace Defense Command (*cf.*  
85 <https://www.celstrak.com/NORAD/documentation/tle-fmt.asp>).

86 The first AVHRR was equipped with four optical channels and was launched in October  
87 1978 on TIROS-N. Subsequently, the sensor was improved to a 5-channel instrument  
88 (AVHRR/2, NOAA-7 through 14) and, for the most recent, 6-channel (AVHRR/3, NOAA-15  
89 through 19). These bands are listed in Table 1, and their strengths and limitations for aerosol  
90 remote sensing are well-established (*cf.* Tanré et al., 1992; Mischenko et al., 1999 for detailed  
91 discussions). In brief, with only two overlapping spectral bands available on most sensors  
92 (channels 1 and 2 centered near 630 and 850 nm, *cf.* Figure 1, Table 1), the ability to infer  
93 aerosol type is very limited. The spectral width of channel 2 in particular is problematic, since it  
94 is a broad band which covers water vapor absorption lines, meaning that ancillary information

95 about column water vapor content is required to make quantitative use of this band. The  
96 AVHRR/3 sensors included a third solar band near 1.6  $\mu\text{m}$  (channel 3a), which improves  
97 fine/coarse aerosol discrimination, although this band was inactive on many AVHRR sensors  
98 (either the 1.6  $\mu\text{m}$  or 3.7  $\mu\text{m}$  channels were in operation, not both simultaneously), and as such is  
99 not considered further at the present time to improve sensor-to-sensor consistency. AVHRR/3  
100 also had the advantage that channels 1 and 2 were narrower and did not significantly overlap  
101 compared to the spectral responses of these bands on AVHRR/2 instruments (*cf.* Figure 1).  
102 Differences between the sensors' spectral response functions make the task of achieving multi-  
103 sensor consistency less straightforward. The remaining three bands (channels 3b, 4, and 5),  
104 centered near 3.7, 11, and 12  $\mu\text{m}$ , are more similar between the AVHRR/2 and AVHRR/3 series  
105 sensors, and are of great utility for applications such as surface/cloud temperature monitoring  
106 and detection of thermally-active aerosols (e.g., mineral dust, volcanic ash). Since AVHRR/1 on  
107 TIROS-N and NOAA-6 has only 4 channels and lacks the 12  $\mu\text{m}$  band, which is needed for our  
108 Deep Blue algorithm, AVHRR measurements before the year 1981 will not be considered.

109         Despite these limitations, AVHRR data have been used for retrieving aerosol optical  
110 depth (AOD) by various groups. Most AOD data sets created from AVHRR measurements are  
111 over-water only, since water surface reflectance in this spectral region is low and can be modeled  
112 with reasonable accuracy as a function of near-surface wind speed. One-channel algorithms such  
113 as described in Rao et al. (1989) and Stowe et al. (1997) use the 630 nm band (avoiding the  
114 difficulties of water vapor absorption in channel 2) but are then restricted to assuming a single  
115 aerosol optical model everywhere, which leads to type-dependent AOD biases. Two- or three-  
116 channel approaches (e.g., Rao et al., 1989; Mishchenko et al., 1999; Ignatov and Stowe, 2002;  
117 Ignatov et al., 2004) permit retrieval of AOD and Ångström exponent (AE), thus providing some

118 indication of aerosol size, although the sensitivity to size remains small and there is essentially  
119 no sensitivity to other parameters such as aerosol absorption. Validation of earlier AVHRR data  
120 sets is limited due to the sparse availability of ground-truth data at these times, although a few,  
121 mostly regional, studies have been performed (e.g. Stowe et al. 1997, Haywood et al. 2001, Zhao  
122 et al. 2002, 2003, 2004). Other studies have focused on more statistical long-term comparisons  
123 with Sun photometers rather than instantaneous matchups (Liu et al., 2004), or on comparison of  
124 overlapping AVHRR time series to assess sensor-to-sensor consistency (Ignatov et al., 2004).

125         Several attempts have also been made to use AVHRR to determine AOD over land, for  
126 which characterization of land surface reflectance presents a significant difficulty. Knapp and  
127 Stowe (2002) proposed a method using Aerosol Robotic Network (AERONET, Holben et al.,  
128 1998) to estimate the surface reflectance in the vicinity of individual sites, and then constructing  
129 surface reflectance models as a function of land cover type. Riffler et al. (2010) take a 45-day  
130 window and essentially use a minimum reflectance technique (with an additional stratification by  
131 viewing zenith angle) to estimate surface reflectance for a given location. Mei et al. (2014) used  
132 ancillary surface information from the Moderate Resolution Imaging Spectroradiometer  
133 (MODIS) in concert with the AVHRR 3.7  $\mu\text{m}$  band (which is comparatively unaffected by the  
134 presence of aerosols) and Normalized Difference Vegetation Index (NDVI, Tucker, 1979) to  
135 infer surface reflectance over China. In all cases, aerosol optical models are prescribed rather  
136 than retrieved, due to the limited information content of the measurements. More recently,  
137 synergistic use of AVHRR with other instruments on board the MetOp platforms has enabled  
138 improved retrieval of AOD over both land and ocean (EUMETSAT, 2016). The combination of  
139 sensors provides additional information content for identification of aerosol type, and

140 discrimination between clouds and heavy aerosols, which ameliorates some of the issues of  
141 AVHRR-only algorithms.

142 As a result of these obstacles, it has been a highly challenging task to retrieve aerosols  
143 globally from AVHRR, particularly over land. Nevertheless, AVHRR instruments provide  
144 valuable measurements from 1981 to the present, a time series which is otherwise not available  
145 from US Earth Observing System (EOS) sensors. Based upon previous results from our Sea-  
146 viewing Wide Field-of-view Sensor (SeaWiFS) Deep Blue aerosol products, we demonstrated  
147 that an algorithm based on NDVI using a pair of red and near infrared channels (e.g., 650 and  
148 865 nm, close to AVHRR channels 1 and 2) can be useful in determining surface reflectance  
149 over vegetated land when shortwave infrared channels (such as 2.1  $\mu\text{m}$ ) are lacking (Hsu et al.,  
150 2013). In order to take advantage of this nearly 40-year long-term time series of AVHRR  
151 records, we develop a new approach, which is a modified version of the Deep Blue algorithm, to  
152 retrieve aerosol properties from AVHRR over land and ocean with similar data structures  
153 following the convention of our SeaWiFS aerosol products. Over ocean the Satellite Ocean  
154 Aerosol Retrieval (SOAR) algorithm, which has been applied to SeaWiFS and Visible Infrared  
155 Imaging Radiometer Suite (VIIRS) measurements (Sayer et al., 2012a, 2017a), is likewise  
156 adapted for use with AVHRR to complement Deep Blue by providing coverage over water  
157 surfaces. Like SeaWiFS, as AVHRR LAC data are not available everywhere, we use the GAC  
158 data in retrieval processing for consistency between satellite platforms.

159 Sensor radiometric calibration plays a key role in constructing long-term climate data  
160 records. This is particularly important for this study, since there is no onboard solar band  
161 calibration for AVHRR. Various approaches have been applied to characterize the absolute  
162 calibration and on-orbit degradation of the instruments. This first version of the AVHRR Deep

163 Blue data products uses the calibration of Vermote and Kaufman (1995), which is also used for  
164 NASA's long-term NDVI time series data products (e.g. Tucker et al., 2005). Vermote and  
165 Kaufman (1995) provide a methodology for the absolute calibration of AVHRR bands 1 and 2,  
166 which is repeated through time to monitor and correct for the degradation of these bands on-  
167 orbit. A first step uses views of high-altitude bright clouds as 'white' reference targets to provide  
168 a relative calibration between the two bands. A second step determines an absolute calibration of  
169 channel 1, using off-nadir pixels over ocean where the aerosol load is low and Rayleigh signal  
170 comparatively high. This absolute channel 1 calibration can then be transferred to channel 2  
171 using the cloud-derived relative calibration between these bands. Other methodologies have been  
172 explored (e.g., Heidinger et al., 2002; Wu et al., 2010; Bhatt et al., 2016), and the use of their  
173 calibrations will be investigated for future versions.

174 In this paper, we describe the details of this new extension of our Deep Blue/SOAR  
175 algorithms to AVHRR. Section 2 summarizes the methodology of the over-land and over-water  
176 algorithms, and detailed changes made in each key component compared to the other  
177 applications of Deep Blue and SOAR. Section 3 illustrates the results of the daily and seasonal  
178 aerosol products generated from the new algorithms and their comparisons with those from  
179 MODIS. Finally, we show provisional validation of the new AVHRR Deep Blue products in  
180 Section 4, followed by some conclusions in Section 5. This paper focuses primarily on the  
181 discussion of retrieval algorithms, while a detailed evaluation of the AVHRR Deep Blue aerosol  
182 product performance using AERONET and other measurements is provided by a companion  
183 paper, Sayer et al. (2017b). In this study, we use data from AVHRR/2 on NOAA-14 and  
184 AVHRR/3 on NOAA-18 to demonstrate its capability of processing both older and newer  
185 AVHRR instruments, although this algorithm can be applied to other AVHRR sensors from

186 NOAA-7 to NOAA-19 as well. AVHRR AOD data have been processed using these algorithms  
 187 for parts of the NOAA-11, NOAA-14, and NOAA-18 missions; more information, including  
 188 download links, can be found at <https://deepblue.gsfc.nasa.gov>.

## 189 190 2. Descriptions of AVHRR Aerosol Retrieval Algorithm

191 To retrieve AVHRR aerosol properties over land and ocean, we employ the Vector  
 192 Linearized Discrete Ordinate Radiative Transfer (VLIDORT; Spurr, 2006) radiative transfer  
 193 model to compute the reflected intensity field, which is defined by

$$194 \quad R(\mu, \mu_0, \phi) = \frac{\pi I(\mu, \mu_0, \phi)}{\mu_0 F_0}, \quad (1)$$

195 where  $R$  is the normalized radiance (or apparent reflectance),  $F_0$  is the extra-terrestrial solar flux,  
 196  $I$  is the radiance at the top of the atmosphere (TOA),  $\mu$  is the cosine of the view zenith angle,  $\mu_0$   
 197 is the cosine of the solar zenith angle, and  $\phi$  is the relative azimuth angle between the direction of  
 198 propagation of scattered radiation and the incident solar direction. This radiative transfer code  
 199 includes full multiple scattering and takes into account polarization. Using VLIDORT, lookup  
 200 tables (LUTs) were generated based upon the spectral response functions of a given AVHRR  
 201 sensor (*cf.* Figure 1) for different solar/viewing geometries and underlying surface (land and  
 202 ocean) boundary conditions for aerosol retrievals.

203 However, before the retrieval, the AVHRR TOA reflectances must first be corrected for  
 204 absorption by ozone, water vapor, and well-mixed gases (details described by Sayer et al.,  
 205 2017a). For this initial version of the data set, gas absorption coefficients from Ignatov and  
 206 Stowe (2002) for NOAA-15 were used (since these values are close to average of those reported  
 207 by that study for NOAA-11, -14, and -18), scaled to account for total column ozone and water  
 208 vapor read in from the MERRA2 reanalysis (Bosilovich et al., 2015). In addition, for our over-

209 water retrievals, near-surface wind speed from MERRA2 is used to take into account the effects  
210 of oceanic whitecaps and Sun-glint strength adequately, as in prior applications of SOAR (Sayer  
211 et al., 2012a, 2017a). After the gas absorption correction, the processing stream is subsequently  
212 split into land or ocean algorithm, according to the MODIS land/sea mask, to account for the  
213 underlying surface boundary conditions in the LUTs. Advantages of MERRA2 include that it is  
214 available for the whole AVHRR record, which enables consistency between processing of  
215 different AVHRR sensors, and is at a higher spatial resolution ( $0.625^\circ$  longitude,  $0.5^\circ$  latitude)  
216 than some other reanalyses.

## 217 218 2.1 Land Algorithm (Deep Blue)

219 Similar to our SeaWiFS/MODIS algorithm, before the aerosol retrieval is performed, we  
220 first screen out the pixels contaminated by the presence of clouds. Due to the lack of the blue  
221 bands and  $1.38 \mu\text{m}$  cirrus channel for AVHRR, the previous MODIS cloud screening module has  
222 been modified to account for the band differences. The schematic diagram of the AVHRR Deep  
223 Blue cloud screening scheme is depicted in Figure 2. We utilize all of the bands that are available  
224 for both AVHRR/2 and AVHRR/3 from visible to thermal infrared wavelengths to fully take  
225 advantage of the spectral information provided by the AVHRR sensor for detecting clouds. As  
226 shown in Figure 2, instead of using the 412 nm channel (available to MODIS and SeaWiFS), a  
227 spatial variability filter based on the TOA reflectance at 630 nm ( $R_{630}$ ) within a  $3 \times 3$  pixel area  
228 is employed for AVHRR. Also, in order to account for the dynamic range of surface reflectances  
229 at 630 nm over different ecosystem types, different threshold values are applied over darker and  
230 brighter surfaces. Based upon our extensive tests, this method is robust in filtering out puffy (e.g.  
231 cumulus) clouds as well as cloud edges. Checks on brightness temperature (BT) at  $11 \mu\text{m}$   
232 (BT11) have been implemented in conjunction to BT difference (BTD) between 11 and  $12 \mu\text{m}$

233 (BTD11-12) tests to effectively detect high or optically-thin clouds. Finally, in order to  
234 distinguish the heavy dust plumes from clouds, we also adopt a heavy dust flag so that the  
235 processing stream will bypass the cloud screening module when this is triggered (i.e., BTD11-12  
236  $< -1.5$  K). These thresholds are empirical, adapted for AVHRR from our prior implementation of  
237 Deep Blue to MODIS (e.g. Hsu et al., 2013).

238 The aerosol optical models used in our AVHRR algorithm are in general consistent with  
239 those in the MODIS and SeaWiFS Deep Blue algorithm (*cf.* Hsu et al., 2004, 2013 for details).  
240 However, there have been a number of changes made in our AVHRR surface reflectance  
241 determination scheme to accommodate the channel differences between AVHRR and  
242 SeaWiFS/MODIS. These changes are summarized below.

#### 243 2.1.1 Determination of Surface Reflectance

244 As demonstrated in our previous results (Hsu et al., 2013), the calculation of surface  
245 reflectance plays a key role in the accuracy of the retrieved aerosol properties. Since AVHRR  
246 has limited channels compared to later, more advanced sensors such as SeaWiFS and MODIS,  
247 the previous Deep Blue surface reflectance determination scheme needs to be modified. Figure 3  
248 depicts the flowchart of our AVHRR surface reflectance estimation module. The details of each  
249 component are described as follows:

##### 250 251 2.1.1.1 Deep Blue Surface Database

252 For urban, dry, and transitional land surfaces, similar to the SeaWiFS/MODIS  
253 applications, a database method is used for determining surface reflectance. This was compiled  
254 based upon the minimum reflectivity method at  $0.1^\circ$  resolution for each season using AVHRR

255 TOA reflectance at 630 nm (*cf.* Hsu et al., 2004 for details). In brief, this approach is designed to  
 256 seek the minimum Rayleigh-corrected TOA reflectance for a certain period of time at each  
 257 location, and uses this as a proxy for surface reflectance. In order to construct a surface database  
 258 for AVHRR, we first apply various tests to filter out pixels contaminated by the presence of  
 259 clouds using cloud screening scheme described above. Reflectances which pass these tests are  
 260 then corrected for the contribution from molecular (Rayleigh) scattering and averaged into a  
 261 daily mean for a given grid cell. Finally, the surface reflectance values in the AVHRR database  
 262 are calculated by a second-order polynomial fit through the lowest 15 percentile of points in a  
 263 given grid cell against the scattering angles of these observations; the scattering angle ( $\Theta$ ) is  
 264 defined as

$$265 \quad \Theta = \cos^{-1}(-\cos \theta_0 \cos \theta + \sin \theta_0 \sin \theta \cos \phi) \quad (2)$$

266 where  $\theta_0$ ,  $\theta$ , and  $\phi$  are the solar zenith, sensor view zenith, and relative azimuth angles,  
 267 respectively. These angular curve fittings of surface reflectance are performed for each NDVI  
 268 group ( $\text{NDVI} < 0.18$ ,  $0.18 \leq \text{NDVI} < 0.35$ , or  $\text{NDVI} \geq 0.35$ ) collected in the given grid cell,  
 269 provided that a sufficient sample size (20 or more points) is acquired. Based on prior experience  
 270 with SeaWiFS and MODIS, this approach and fit type was found to be able to accurately capture  
 271 the main angular variations in surface reflectance.

272 Figure 4 shows the derived global 630 nm surface reflectance maps for NOAA-18  
 273 AVHRR, based upon five years (2006-2010) of AVHRR data, for each season using the above  
 274 approach. Due to limited AVHRR channels and information content the surface database is  
 275 constructed over both land and ocean in order to help identify the turbid water for the SOAR  
 276 algorithm (Section 2.2). For the AVHRR over-land algorithm, the surface reflectance is

277 determined using the database approach over moderately bright arid and urban regions where  
278 630 nm surface reflectance is between 0.15 and 0.30 (Figure 3). As discussed in e.g. Hsu et al.  
279 (2004) and Seidel and Popp (2012), aerosol signals diminish when the surface reflectance  
280 reaches the critical surface reflectance; for the 630 nm wavelength this includes many arid and  
281 semi-arid regions, such as parts of the Sahara Desert and Arabian Peninsula, as well as snow/ice-  
282 covered land. Over these types of surfaces, we cannot accurately retrieve aerosol properties using  
283 measurements from single-view satellite sensors with this wavelength. However, 630 nm surface  
284 reflectances over arid regions in China and Mongolia are not as bright as those in the Sahara and  
285 Arabian Peninsula, and are in general less than 0.30 (Figure 4). Consequently, we exclude pixels  
286 over the deserts and semi-deserts in North Africa for retrievals, but include those over dry  
287 regions in China and Mongolia where the surface reflectance at 630 nm is below the critical  
288 values and thus suitable for aerosol retrievals. Finally, if BTD11-12 is more negative than -1.5 K,  
289 AOD retrieval will be performed regardless of surface condition, since for thick dust plumes the  
290 majority of the satellite signal comes from atmosphere. Figure 5 shows the geographic regions  
291 where different approaches are used for surface reflectance. As described above the database  
292 method is used over urban, dry, or transitional land surfaces, while a NDVI method (introduced  
293 below) is used over vegetated areas.

#### 294 2.1.1.2 Vegetated Land Surfaces

295 The phenological cycle of vegetation (growth and senescence) means that the reflectance  
296 of vegetated surfaces can vary rapidly, particularly compared to barren surfaces such as deserts.  
297 Therefore, it is important to determine surface reflectance at a high temporal resolution to  
298 minimize errors in AOD related to changing surface characteristics. In this regard, the AVHRRs  
299 have a weakness compared to the MODIS and VIIRS sensors, in that the latter two include

300 shortwave infrared (SWIR) bands, useful for estimating surface characteristics on an  
 301 instantaneous basis, which AVHRR lacks.

302         SeaWiFS has a similar limitation. However, based upon our previous SeaWiFS Deep  
 303 Blue retrievals, we found that the NDVI can serve as a useful proxy to estimate surface  
 304 reflectance, making it possible to instantaneously derive surface reflectance and thus AOD in  
 305 both blue (490 nm) and red (670 nm) bands (Hsu et al., 2013; Sayer et al., 2012b). Although the  
 306 670 nm AOD showed an AOD-dependent underestimation, the 490 nm AOD, which showed  
 307 negligible bias, could be used to correct the 670 nm AOD. For AVHRR, our preliminary  
 308 investigations (not shown) suggested that the NDVI approach resulted in a more significant bias  
 309 in 630 nm AOD than SeaWiFS. Since there is no additional band in AVHRR to correct for the  
 310 bias (unlike SeaWiFS), we have developed a modified NDVI-based method to determine surface  
 311 reflectance for AVHRR, which merge the use of NDVI with the concept of minimum reflectance  
 312 approach used in our Deep Blue surface database construction mentioned above.

313         Although similar to the minimum reflectance technique, this method utilizes NDVI rather  
 314 than TOA reflectance when determining the ‘clean’ background condition. The Rayleigh-  
 315 corrected NDVI ( $NDVI_{RC}$ ) is defined as

$$316 \quad NDVI_{RC} = \frac{R_{RC,band2} - R_{RC,band1}}{R_{RC,band2} + R_{RC,band1}}, \quad (3)$$

317  
318

319 where  $R_{RC,band1}$  and  $R_{RC,band2}$  are Rayleigh-corrected TOA reflectances in bands 1 (630 nm) and 2  
 320 (850 nm), respectively. The use of NDVI is to avoid extra dimensions for observation geometry  
 321 when deriving surface reflectance, thereby minimizing the search window. Since the surface  
 322 reflectance is strongly dependent on observation geometry, the minimum reflectance only  
 323 represents surface reflectance for the specific observation geometry for which the minimum

324 reflectance is observed. Figure 6 shows AVHRR Rayleigh-corrected TOA reflectance in band 1  
 325 and  $NDVI_{RC}$  for two consecutive orbits on a relatively clean day over the U.S. The  $NDVI_{RC}$   
 326 exhibits a much smaller dependence on observation geometry than the Rayleigh-corrected TOA  
 327 reflectance indicating that ‘clean’ conditions (i.e. cloud-free, low AOD) can be chosen by  
 328 compositing only temporal samples for NDVI, in contrast to needing both temporal and angular  
 329 samples for the TOA reflectance. This is because the ratio in the NDVI definition decreases the  
 330 angular dependence of the signal.

331 Consequently, the surface database is created by searching for maximum NDVI (as  
 332 maximum NDVI corresponds to minimum band 1 surface reflectance) in each 30-day temporal  
 333 window and  $0.1^\circ \times 0.1^\circ$  grid box. The dates of the maximum NDVI are also stored to interpolate  
 334 (linearly) the NDVI values for the dates in between. The surface reflectance in band 1  
 335 ( $R_{sfc,band1}$ ) can then be calculated as

$$336 \quad R_{sfc,band1} = \frac{1-NDVI_{database}}{1+NDVI_{database}} R_{RC,band2}, \quad (4)$$

337  
338

339 where  $NDVI_{database}$  is the maximum NDVI stored in the database. As can be inferred from Eq.  
 340 (4) the angular dependence of the 630 nm surface reflectance is described by the instantaneous  
 341 850 nm TOA reflectance in this approach. Figure 7 shows the 30-day maximum NDVI database  
 342 created for the year 2006 and four day of year (DOY) windows 1-30, 91-120, 181-210, and 271-  
 343 300, representative for boreal winter, spring, summer, and fall, respectively. The seasonal  
 344 variation and spatial pattern of NDVI indicate reliability of a 30-day window. We also  
 345 investigated (not shown) temporal windows between 10 and 45 days, although neither showed  
 346 superior performance over the 30-day window in every aspect. Shorter temporal windows tended  
 347 toward an underestimation in AOD due to the remaining aerosol signal in the NDVI database,

348 while longer temporal windows tended toward overestimation by choosing more densely  
349 vegetated conditions than representative for the bulk of the period.

350         Since the NDVI database is susceptible to the residual aerosol signal on the day chosen  
351 for the database, an aerosol correction needs to be applied to the database to alleviate the  
352 aforementioned underestimation in AOD. To this end, atmospheric correction is performed for  
353 AVHRR band 1 and band 2 TOA reflectances to derive atmosphere-corrected (for both Rayleigh  
354 and aerosol contributions) NDVI, denoted  $NDVI_{Ac}$ , and compare with  $NDVI_{Rc}$ . AVHRR  
355 observations are collocated with AERONET sites over North America for the period from 2006  
356 to 2011 with a spatial window of  $0.1^\circ$  in latitude and longitude and a temporal window of 30 min.  
357 Then, the atmospheric contribution to TOA reflectance is removed using radiative transfer  
358 calculations utilizing the AERONET-observed spectral AOD as input. For AERONET, cloud-  
359 screened and quality-assured Level 2 direct Sun measurements (Smirnov et al., 2000; Holben et  
360 al., 2006) were used, and AOD at AVHRR band 1 and 2 were derived from the spectral AOD  
361 and AE over the 440-870 nm wavelength range. The comparison between  $NDVI_{Ac}$  and  $NDVI_{Rc}$   
362 provides useful information for the aerosol correction scheme.

363         Figure 8 shows differences between  $NDVI_{Ac}$  and  $NDVI_{Rc}$  as a function of 550 nm AOD,  
364  $NDVI_{Rc}$ , air mass parameter (AMP,  $\sec\theta_o \times \sec\theta_v$ ), and scattering angle, which are factors on  
365 which the aerosol signal is dependent. Also shown are the differences after applying corrections  
366 for aerosol signals described here. The NDVI differences before the corrections reveal that the  
367 aerosol contamination in the  $NDVI_{Rc}$  is strongly dependent on AOD and results in negative  
368 biases. Relatively weak dependences are also found on NDVI, AMP, and scattering angle. It  
369 should be noted that in addition to the strong dependence on AOD, the absolute difference  
370 between  $NDVI_{Rc}$  and  $NDVI_{Ac}$  generally increases with increasing NDVI and decreasing

371 scattering angle up to  $\sim 120^\circ$ . The dependence on AMP is less significant. This is because both  
 372 increasing NDVI and decreasing scattering angle enhance the aerosol signal at a given AOD, due  
 373 to increasing contrast between aerosol and surface signals, and increasing aerosol scattering  
 374 intensity, respectively. By the same reasoning, a dependence on AMP is also expected (due to  
 375 increasing aerosol signal with air mass), but the dependence is much smaller than those of the  
 376 other parameters. This is likely due to the contextual characteristics of the bias and sensitivity.

377 Trial and error based on the median differences between  $NDVI_{RC}$  and  $NDVI_{Ac}$  leads us to  
 378 the following correction equations:

379 For scattering angle  $\geq 120^\circ$ ,

380

$$381 \quad NDVI_{RC,corrected} = NDVI_{RC} + [0.23 + 0.15 \times (AMP - 1)] \times AOD_{550} \times NDVI_{RC} \quad (5)$$

382

383 For scattering angle  $< 120^\circ$ ,

384

$$385 \quad NDVI_{RC,corrected} = NDVI_{RC} + [0.23 + 0.15 \times (AMP - 1) + 0.03 \times (120^\circ - \theta)] \times AOD_{550} \times NDVI_{RC} \quad (6)$$

386

387 It is found that these corrections significantly improve the medians and central 68% intervals of  
 388 the NDVI differences (i.e. medians closer to zero and spread of distribution smaller).

389 In actual implementation, since ‘true’ background AOD values are not available for each  
 390 location and time, a monthly AOD climatology (one value for each of the 12 calendar months,  
 391 not one value for each month of the satellite record) is created using the Aqua MODIS Collection  
 392 6 Deep Blue AOD product. Specifically, the 5<sup>th</sup> percentiles of 13-year Level 3 daily AOD record  
 393 from 2003 to 2015 in each  $1^\circ \times 1^\circ$  grid were chosen to represent the background AOD and used  
 394 to correct the NDVI database using Eqs. (5) or (6) depending on scattering angle. It should be  
 395 noted that the climatology was created in a way to correct the NDVI database a marginal amount,  
 396 such that the different spatial resolution between the NDVI database ( $0.1^\circ$ ) and AOD

397 climatology ( $1^\circ$ ) did not generate a noticeable checkerboard pattern in the spatial distribution of  
398 AOD. Likewise, it is expected that the use of a single monthly climatology for the entire  
399 AVHRR record would not lead to significant biases. Note that this does not mean that the  
400 MODIS Deep Blue record ‘feeds in’ to the AVHRR record on an instantaneous basis, only to  
401 correct the background AOD for the NDVI database calculation as described above. Other  
402 aerosol data sets could in principle be used to create this background AOD climatology instead.  
403 In this way the actual AVHRR AOD retrieval remains largely independent of the MODIS Deep  
404 Blue AOD retrieval.

405         The performance of the surface reflectances derived from the NDVI database is evaluated  
406 by comparing against the atmospherically-corrected TOA reflectances calculated above. Here  
407 data with 550 nm AOD from AERONET  $< 0.2$  are only compared to minimize uncertainties in  
408 the atmospheric correction procedure. As shown in Figure 9, the NDVI database-derived surface  
409 reflectances (estimated surface reflectances) are well-correlated with the atmosphere-corrected  
410 TOA reflectances (benchmark surface reflectances) in general, showing root-mean-square error  
411 (RMSE) ranging from 1.70% to 2.67% and mean bias (MB) from -0.38% to -0.92% (excluding  
412 winter due to the small number of data points). This performance is more than acceptable given  
413 the fact that the surface reflectances for AVHRR are from a database at a 30-day temporal  
414 resolution rather than instantaneous values (although interpolated between nodes). The outliers  
415 (with low number density) are largely due to this temporal limitation of the database approach.  
416 These outliers are from a few locations at which the database method is less optimal, and thus  
417 would not significantly affect a large-scale view of the aerosol product. For instance, AERONET  
418 sites located near croplands, such as Bondville (Illinois, U.S.) and Egbert (Ontario, Canada), and  
419 near complex environment, such as Billerica (near Boston, U.S.) contribute to a large portion of

420 the outliers. It should be noted that in the Level 2 aerosol data product the effect of the outliers,  
421 especially due to spatial inhomogeneity, would be mitigated by the spatial aggregation ( $2 \times 2$   
422 pixels), as Figure 9 compares data at different spatial resolutions ( $0.1^\circ$  for the surface database,  
423 L1B resolution for the benchmark).

424 The application of our NDVI-based land algorithm is limited to certain surface and  
425 viewing geometry conditions, due to the use of single 630 nm band in retrieving AOD. Through  
426 extensive investigation on retrieval sensitivities and error characteristics of AOD, we have  
427 chosen the following procedures to select retrieval pixels for this approach:

428 i) 630 nm surface reflectance is lower than 0.15, and International Geosphere-Biosphere  
429 Programme (IGBP) land cover type (Friedl et al., 2010) is not classified as ‘open shrublands’,  
430 ‘grasslands’, or ‘croplands’. Because AOD retrieval sensitivity decreases with increasing surface  
431 reflectance, data are excluded when surface reflectance is too high.

432 ii) If IGBP land cover type falls into the three categories in i), air mass factor needs to be higher  
433 than 2.5 in addition to the surface reflectance criterion for the pixel to be eligible for retrieval. It  
434 is found that AOD retrieved over these three land cover types are less accurate compared to that  
435 over other land cover types, mainly due to higher surface reflectance values (although less than  
436 0.15) and higher uncertainty of estimating surface reflectance over these regions. This requires  
437 the additional filter to only include data with high signal-to-noise ratio, which reduces artificial  
438 hotspots resulting from errors in calculated surface reflectance combined with weak aerosol  
439 signal.

440 2.1.2 AOD Determination and Extrapolation to 550 nm

441           After the surface reflectance is determined based upon surface types as described above,  
442 a maximum likelihood method is used with pre-calculated LUTs to match the appropriate values  
443 of AOD to the measured reflectances from AVHRR, based on these surface reflectances and the  
444 aerosol optical models as used for other satellite sensors (Hsu et al., 2004). This is the same basic  
445 approach as used for SeaWiFS/MODIS Deep Blue, except for the different available spectral  
446 bands. Note that the 630 nm band is used for the inversion, and thus the retrieved AOD is also at  
447 630 nm. For details of the algorithm see Hsu et al. (2004, 2013).

448           Since 550 nm AOD is the primary product of the Deep Blue algorithm for other satellite  
449 sensors, and is widely used within the aerosol community, the 630 nm AOD is extrapolated to  
450 550 nm using an AE climatology. This saves the data user from having to perform such an  
451 extrapolation themselves. The climatology is created from the full Level 2 AERONET record  
452 available at the present time. Specifically, multi-year monthly median 440-870 nm AE values at  
453 each AERONET site are calculated based on daily median values, when the numbers of data  
454 points are higher than 5 for both the daily and monthly calculations. The monthly climatology is  
455 then expanded globally to a  $1^\circ \times 1^\circ$  grid using exponentially weighted means of the medians  
456 from the AERONET sites. For the weighting factor, e-folding lengths of 500 km for longitude  
457 and 250 km for latitude are used (to account for prevailing zonal winds over the globe). It was  
458 found that the background AOD from AERONET can be accurately interpolated regardless of  
459 the e-folding length in the range of 100-1000 km (Zhang et al., 2016), although the error can  
460 increase over areas where AERONET sites are sparsely distributed. It should be noted that the  
461 single channel retrieval of AVHRR leads us to using a seasonal aerosol optical model in each  
462 geographic region rather than retrieving it in each pixel, such that extrapolation of AOD using  
463 the optical models is not optimal.

## 464 2.2 Ocean Algorithm (SOAR)

465 The over-water AOD retrieval is based on the same SOAR algorithm applied previously  
466 to SeaWiFS and VIIRS observations, simplified to account for the more limited measurement  
467 capabilities of the AVHRR sensors. Full details of SOAR are provided by Sayer et al. (2012a,  
468 2017a), and a summary of key points is below.

### 469 2.2.1 Selection of Suitable Pixels

471 Pixels contaminated by Sun-glint, clouds, or suspected of excessively turbid water are  
472 excluded from processing; Sun-glint masking is as described in Sayer et al. (2012a) but cloud  
473 and turbid water masks are different due to the different spectral bands available to AVHRR.  
474 Pixels are identified as cloudy if they are either bright (band 1 TOA reflectance  $> 0.08$ ), cold ( $12$   
475  $\mu\text{m}$  BT  $< 270$  K), or heterogeneous ( $3 \times 3$  pixel standard deviation of TOA reflectance  $> 0.005$   
476 for either band 1 or band 2). To minimize contamination from undetected cloud or 3D effects,  
477 pixels adjacent to a pixel identified as cloudy are also excluded. These thresholds have been  
478 determined empirically and tested to ensure both few false negatives (i.e., undetected cloud) and  
479 positives (i.e., over-screening of aerosol plumes).

480 Pixels are identified as persistently turbid (or potentially land-contaminated) and  
481 excluded if the seasonal Deep Blue surface reflectance database value at 630 nm is above 0.06  
482 (Section 2.1.1.1). This typically removes 0-2 pixels on some coastlines, except for areas of  
483 larger-scale turbidity such as the Bay of Bengal or mouth of the Amazon River. If such pixels are  
484 not excluded then the effect is a positive bias in retrieved AOD, as AVHRR unfortunately has  
485 insufficient information content to easily distinguish between turbid water and elevated aerosol  
486 loading.

## 487 2.2.2 Pixel-Level Retrieval

488 As with prior applications of SOAR (Sayer et al., 2012a, 2017a), individual pixels are  
489 used to retrieve aerosol properties in a multispectral weighted least-squares fit of observed TOA  
490 reflectances against pre-computed values stored in LUTs. The SeaWiFS and VIIRS applications  
491 simultaneously retrieved the AOD at 550 nm and fine mode fraction (FMF) as well as the best-fit  
492 aerosol optical model (which consists of bimodal size distribution parameters and spectral  
493 complex refractive index), from which other parameters like AE can be derived in a self-  
494 consistent manner. As only two measurements are available for AVHRR, only the AOD and  
495 best-fit aerosol optical model are retrieved and the FMF is fixed for each aerosol optical model.  
496 The LUT is generated with the VLIDORT radiative transfer code (Spurr, 2006) and aerosol  
497 model information is provided in Table 2 (including references for optical model parameters).  
498 Use of these models keeps a level of consistency with other applications of SOAR: other over-  
499 ocean AOD retrievals for AVHRR typically retrieve AOD and AE but assume the same aerosol  
500 size distribution/refractive index globally (e.g., Mishchenko et al., 1999; Ignatov and Stowe,  
501 2002), which is a slightly different approach to aerosol ‘typing’. To allow some more flexibility  
502 in distinguishing low-AOD conditions between open oceans and continental outflow regions,  
503 where FMF may be different (e.g., Smirnov et al., 2011), there are two maritime models with  
504 different FMF permitted (but otherwise the same AOD range and modal optical properties).  
505 Different LUTs are calculated for each AVHRR sensor, as their central wavelengths and  
506 bandwidths are different (e.g., Tanré et al., 1992).

507 The ocean surface reflectance model used is described in Sayer et al. (2017a), which is an  
508 updated version of that from Sayer et al. (2012a), incorporating more recent measurements of  
509 optical characteristics of water and pigments. A  $\log_{10}$  chlorophyll concentration ( $\text{mg m}^{-3}$ ) of -0.5

510 is assumed, although the surface reflectance over AVHRR bands is only weakly dependent on  
511 this over the range of typical oceanic chlorophyll concentrations. As such this approximation  
512 should add negligible ( $<0.01$ ) additional uncertainty in retrieved AOD.

513         The retrieval minimizes the sum of the squared deviation between measurements and  
514 LUT values, weighted by assumptions of the uncertainty in the AVHRR bands (from calibration,  
515 gas correction, and the forward model), providing essentially a  $\chi^2$  statistic referred to as the  
516 retrieval cost. At present these relative uncertainties are assumed to be 3% for band 1 and 20%  
517 for band 2; this deweighting of band 2 is to account for the greater calibration and gas absorption  
518 uncertainties with this band. As a result the AOD is mostly determined by band 1, while band 2  
519 provides some constraint on best-fit aerosol optical model. In version 1 of the AVHRR data set,  
520 the TOA reflectances have also been scaled for NOAA-14 (by 0.95 and 0.89 for bands 1 and 2)  
521 and NOAA-18 (by 0.97 and 0.95) based on validation against AERONET and examination of  
522 maps of aerosol model choices. This is an empirical step taken as a first-pass to decrease  
523 potential systematic uncertainties related to the sensor calibration used and trace gas absorption,  
524 which will hopefully be improved upon for future versions once the different available multi-  
525 sensor AVHRR calibrations have been evaluated for aerosol processing. Note that the NASA  
526 NDVI products which also use the Vermote and Kaufman (1995) calibration methodology also  
527 apply further empirical corrections, although at the NDVI stage rather than the level 1 stage  
528 (Tucker et al 2005, and references therein), so such adjustments are not unprecedented.

### 529 2.3 Aggregation to $2\times 2$ Cell Resolution and Quality Flags

530         Over both land and ocean, after the retrieval, the AOD and other parameters are  
531 aggregated to  $2\times 2$  ‘cell’ resolution, which is the output resolution for the Level 2 product, and

532 corresponds to approximately  $8.8 \times 8.8 \text{ km}^2$  horizontal pixel size at the sub-satellite point  
533 (although see prior discussion on LAC/GAC sampling). The median of all retrieved quantities is  
534 taken (to reduce sensitivity to, e.g., any residual cloud contamination) from the up to 4 available  
535 pixels. Over ocean, the aerosol model with the lowest cell-average cost is chosen as the ‘best’  
536 solution, and this is reported in the Level 2 product. The main retrieved quantity is the AOD at  
537 550 nm and AVHRR band 1; over ocean, related information derived from the aerosol optical  
538 model (AOD at AVHRR band 2, FMF, and AE) are also provided.

539         Following the convention used in MODIS/SeaWiFS Deep Blue products, the quality  
540 assurance (QA) flags in AVHRR Level 2 data also have 4 different levels where QA=0 indicates  
541 no retrieval, QA=1 indicates a possible problem with retrieval, and 2/3 indicate moderate and  
542 high quality (i.e., no reason to suspect a problem) respectively. Note that over ocean there is no  
543 QA=2 category. Over ocean, a cell is assigned QA=3 if the retrieval cost is less than 5 (i.e. a  
544 good fit between measurements and forward-modeled reflectances was obtained), at least 2 (out  
545 of 4) pixels within the cell were used in the retrieval, and the AOD standard deviation in the cell  
546 is less than 1. In practice the requirement for at least 2 out of 4 pixels is the most restrictive. Over  
547 land, the AOD standard deviation requirement is stricter (0.35 and 0.20 for QA=2 and 3,  
548 respectively), due to the greater difficulty in AOD retrieval over land, and the pixel count  
549 requirement is the same as over ocean. Since potentially there still could be cloud contamination  
550 in the QA=1 cells, only QA=2 or 3 cells are propagated into Level 3 aggregated data, and in  
551 general only QA=2 or 3 retrievals should be used for most applications.

552     3.     Results and Discussions

553 Figure 10 illustrates one of the examples of our AVHRR AOD products and its  
554 comparison with MODIS Aqua over South America as well as the surrounding water on  
555 September 7, 2006. For MODIS, over-land data from the Deep Blue algorithm are used (Hsu et  
556 al., 2013; Sayer et al., 2013). Over water, the Dark Target MODIS ocean retrieval product (Tanré  
557 et al., 1997; Levy et al., 2013) is used, as SOAR has not yet been applied to MODIS. Our newly  
558 developed AVHRR algorithm, shown in Figure 10 (c), extends the spatial coverage of current  
559 AVHRR AOD products, which are only available over water, to the land surface types. The  
560 AVHRR data shown here are based upon measurements from NOAA-18 with a local solar  
561 equator crossing time of ~2:00 pm, which is slightly later than the 1:30 pm equator crossing time  
562 for Aqua. Nevertheless, the areas of high AOD in our AVHRR image correspond well to the  
563 smoke plumes visible in the MODIS true-color image, capturing the heavy smoke transported  
564 southward. We also compare the AOD values at 550 nm derived from our AVHRR data with  
565 those based upon the MODIS/Aqua aerosol retrievals for the corresponding day, as shown in  
566 Figure 10 (b). The results indicate that the AOD values from these two sensors are quite  
567 comparable, despite their differences in observation time.

568 We also examined algorithm results over Asia, which often exhibits the most complex  
569 aerosol conditions observed, with a mixture of dust and fine mode pollution particles. One such  
570 example, shown in Figure 11, is for April 16, 2006. On this day, a transported dust plume  
571 observed over western and central China around 40° N, 80°–114° E occurred as a result of a  
572 springtime dust outbreak event over the Taklamakan Desert as well as Inner Mongolia. While  
573 this plume was well captured by our AVHRR data, the spatial coverage is sparser over arid  
574 regions around 40° N, 80°–105° E compared to the MODIS data. This is due to the use of air  
575 mass filter applied to the AVHRR retrievals over arid areas. East of this dust plume, the region

576 was covered by widespread fine mode pollution extending all the way to the East China Sea and  
577 the Yellow Sea; the elevated AVHRR AOD values over this area reflect this.

578 In addition to the daily data, we also compare the AVHRR and MODIS products on the  
579 seasonal basis. Figure 12 provides the maps of seasonal averaged AOD from both AVHRR  
580 (NOAA-18) and MODIS (Aqua). These composites were created by taking daily Level 3  
581 products, and then averaging these first to monthly, and then monthly to seasonal, time steps. To  
582 stop poorly-sampled grid cells from introducing potentially significant sampling error into the  
583 comparison, a daily grid cell was considered valid for an instrument if it contained at least 5  
584 retrievals passing QA checks, and a grid cell was considered valid on a monthly basis if it  
585 contained at least 3 valid days. These thresholds are somewhat subjective but, particularly for  
586 cloudy regions, provide a reasonable balance between data coverage and sampling representivity.

587 As shown in Figure 12, both AVHRR and MODIS reproduce the same major spatial and  
588 seasonal variations in aerosol loading. For example, there were intense wild fires over Siberia, in  
589 the summer of 2006, producing heavy smoke plumes all the way into the Arctic Ocean, as seen  
590 in the retrieved June-July-August AOD maps from both sensors. The patterns of elevated aerosol  
591 loading due to anthropogenic air pollution in East Asia and South Asia are also clear in both  
592 sensors throughout the year. The seasonal north-south movement of the Saharan dust transport  
593 displayed in the AVHRR maps is also in agreement with that in the MODIS maps. More detailed  
594 comparisons with the MODIS aerosol products are provided in the companion paper, Sayer et  
595 al.( 2017b).

596 Seasonal means can be influenced by sampling frequency of the given dataset. AVHRR  
597 and MODIS sensors have (to a first order) similar swath widths and similar Level 2 pixel sizes,

598 so it would be expected that sampling frequencies would be similar. Figure 13 confirms that on a  
599 general basis this is indeed the case, and also reinforces the extent to which cloud cover,  
600 snow/ice, and polar night can limit coverage from all instruments of these types (many grid cells  
601 have fewer than 25% of days providing data within a season). Overall AVHRR coverage, while  
602 sharing similarities to that of MODIS, is often around 10% less frequent. This is due to the more  
603 limited information content of the sensor, meaning that cloud screening and QA checks are  
604 stricter in AVHRR to minimize the chances of poor-quality retrievals propagating into the data  
605 product. Coverage in the Sahara and Arabian Peninsula is also limited or absent in AVHRR, as  
606 this surface is too bright in most cases to perform an AOD retrieval from this type of sensor from  
607 the available bands (Section 2.1.1). In AVHRR coverage-sparse regions such as this, sampling  
608 differences are also therefore likely to be playing a role in differences in the seasonal AOD  
609 observed by the two sensors.

610 Figure 14 shows a comparison of multiannual mean AOD at 550 nm from our NOAA18  
611 AVHRR, SeaWiFS (version 4), and MODIS Aqua (Collection 6) aerosol products for their  
612 common overlap period (2006-2010). Note the MODIS ocean data are from the standard Dark  
613 Target group ocean product (Levy et al., 2013); otherwise, all land data shown are Deep Blue,  
614 and ocean data are SOAR. Similar patterns in the mean AOD are seen in all data sets. MODIS  
615 has the highest coverage; AVHRR has more gaps due to the sensor's limitations at discerning the  
616 aerosol signal over the brightest desert surfaces, as discussed, as well as the more conservative  
617 cloud screening (due to more limited spectral channels) reducing coverage over tropical forests.  
618 SeaWiFs has similar cloud-screening limitations due to a lack of any thermal IR bands. SeaWiFS  
619 also, at this point, represents the oldest of the three Deep Blue algorithm versions and has some  
620 additional coverage gaps because of this (Sayer et al. 2012b; Hsu et al. 2013). Some differences

621 in AOD magnitudes result, as in the seasonal comparisons above, from these sampling  
622 differences.

623 Over water, the AVHRR and SeaWiFS data are quite comparable. Validation exercises  
624 have shown that both have near-zero biases in open-ocean conditions, and slight negative biases  
625 in high-AOD conditions (Sayer et al. 2012a, 2017b). Over ocean MODIS shows the same spatial  
626 patterns but with a generally higher AOD. As noted, this is not from the SOAR algorithm. The  
627 standard MODIS Collection 6 over-ocean AOD product is known to have a positive bias in low-  
628 AOD conditions (of order 0.01-0.02; Sayer et al. 2012d, Levy et al. 2013), and a more variable  
629 positive bias in dust-laden conditions due to the lack of a non-spherical dust optical model (e.g.  
630 Mishchenko et al., 1997, Levy et al., 2003, Banks et al., 2017, Lee et al., 2017). Therefore, these  
631 patterns are broadly consistent with the known characteristics of each data set. Additional  
632 comparisons are provided in the comparison data set evaluation paper, Sayer et al. (2017b).

#### 633 4. Validation against AERONET AOD

634 Figure 15 shows scatter density plots providing a global summary of the validation of  
635 AVHRR retrievals based upon 6 years (2006-2011) of NOAA-18 data and 5 years (1995-1999)  
636 of NOAA-14 data over land and ocean. For NOAA-18 a total of 40 sites contributed to over-  
637 ocean data, and 427 over land data; for NOAA-14 the numbers are 20 and 123 respectively.  
638 Because there are fewer AERONET sites before the year 2000, fewer matchup data points are  
639 found for NOAA-14 compared to those for NOAA-18. Full details of the validation are provided  
640 by Sayer et al. (2017b), but a summary is given here. AVHRR and AERONET data are  
641 compared using the standard technique of averaging satellite data within 25 km of the  
642 AERONET site and AERONET data within 30 minutes of the satellite overpass, to decrease the

643 effect of spatiotemporal sampling differences. The AERONET direct-Sun Version 2 Level 2  
644 (cloud-screened and quality assured; Smirnov et al., 2000) data products are used. This  
645 comparison shows results for AVHRR band 1 AOD (near 630 nm). AERONET does not  
646 measure this wavelength directly, so the bands are interpolated spectrally, which adds negligible  
647 additional uncertainty to the approximate 0.01 AOD uncertainty of the AERONET direct-Sun  
648 measurement.

649 For both NOAA-18 and -14 AVHRR data, the correlation coefficients are high in all  
650 cases, and the median biases fairly small. The statistic  $f$  indicates the fraction of points matching  
651 AERONET within the expected error (EE), an envelope of  $\pm(0.03+15\%)$  over ocean and  
652  $\pm(0.05+25\%)$  over land for this first version, on global average for both surface types. While  
653 the exact sensitivity to various assumptions is quite dependent on the context of each individual  
654 retrieval (i.e. aerosol loading and type, surface cover type, solar/view geometry, etc), these EE  
655 envelopes provide a guideline first-order expectation of retrieval performance. They are based  
656 on prior applications of the Deep Blue and SOAR algorithms, and the known limitations of the  
657 AVHRR sensors (cf. Rao et al., 1989; Tanré et al., 1992; Mishchenko et al., 1999, Hsu et al.  
658 2004, 2013; Sayer et al. 2012a,b, 2017b). Specifically, proportion of retrievals within the  
659 expected error calculated separately for regions over ocean, vegetated land only and entire land  
660 are 73.9%, 77.0%, and 73.5% (NOAA-18) and 64.3%, 79.4% and 73.9% (NOAA-14),  
661 respectively. Uncertainties over ocean are smaller than those over land, due in large part to the  
662 darker surface signal. Over land, performance is better when the data are subset to show only  
663 vegetated matchups, for the same reason. These results demonstrate the applicability of the Deep  
664 Blue and SOAR algorithms to AVHRR measurements.

665 5. Conclusion

666 To understand the effects of aerosols on climate and human health, satellite observations  
667 are crucial in providing continuous temporal and spatial sampling of aerosol properties from  
668 source to sink regions for such studies. With the advent of the EOS-era sensors in the late 1990s,  
669 an accurate long-term aerosol dataset from these well-calibrated satellite measurements became  
670 possible. However, for many climate studies the EOS data records are not always of sufficient  
671 length to adequately address the question of long-term aerosol changes on regional/global scales.  
672 Therefore, results using earlier satellite sensors such as AVHRR, which provide nearly 40 years  
673 of measurements, are highly desirable in order to extend the dataset for use in these studies. This  
674 earlier time period (from 1981 to 2000) before the launch of EOS satellites is particularly  
675 important for understanding changes in the levels of aerosol loading over Asia, where a large  
676 fraction of global economic growth over the past several decades has occurred.

677 In this paper, we demonstrated a new approach to quantitatively retrieve, for the first  
678 time, this much needed aerosol information from AVHRR over land and ocean on a global scale.  
679 Our approach is an extension of the SeaWiFS/MODIS Deep Blue and SOAR aerosol algorithms.  
680 Over land, we merge the use of NDVI with the framework of the minimal reflectance method to  
681 account for the effects of changing vegetation in surface reflectance. Over ocean, a simplified  
682 version of SOAR is employed for aerosol retrieval. Using these algorithms, our results show that  
683 daily, seasonal, and annual distributions of AOD from AVHRR are in reasonable agreement with  
684 those from MODIS, despite the limitations on its information content. The cloud screening  
685 scheme for AVHRR is also shown to be robust in distinguishing heavy aerosol plumes from  
686 clouds, based upon the results of intercomparing daily AOD data from AVHRR and MODIS.

687 Extensive comparisons have also been performed between the AOD values retrieved  
688 from the AVHRR instruments on NOAA-14 and -18 and the AERONET data. Using the

689 calibration of Vermote and Kaufman (1995), our AVHRR AOD values show good agreement  
690 with the AERONET data over land and ocean for both the NOAA-14 (1995-1999) and NOAA-  
691 18 (2006-2011) time periods. Based upon these comparisons, the expected error is estimated to  
692 be  $\pm(0.03+15\%)$  over ocean and  $\pm(0.05+25\%)$  over land for this first version of AVHRR aerosol  
693 products. Detailed evaluations of the AVHRR products are included in a companion paper  
694 (Sayer et al., 2017b). For the next step, we plan to process the AVHRR time series by employing  
695 different calibrations (e.g., Heidinger et al., 2002; Wu et al., 2010; Bhatt et al., 2016) to examine  
696 the sensor-to-sensor consistency using the multiple overlapping years of data in order to ensure  
697 the long-term stability of the aerosol data records.

698 Multiple years of the AVHRR Deep Blue aerosol products from NOAA-11, -14 and -18  
699 are now available via the Deep Blue project web site (<https://deepblue.gsfc.nasa.gov>). This  
700 dataset will eventually be able to provide nearly 40 years of aerosol data records from AVHRR  
701 not only over ocean, but also over the entire cloud-free, snow/ice-free land area, except for very  
702 bright desert regions such as the Sahara and arid regions in the Arabian Peninsula. When  
703 combined with data from EOS-era sensors such as SeaWiFS and MODIS, our AVHRR record  
704 will provide a critical piece in the construction of a consistent long-term aerosol data record for  
705 deriving aerosol trends on both global and regional scales.

706

## 707 **Acknowledgements**

708 This work was supported by the NASA Radiation Sciences Program, managed by Dr. Hal  
709 Maring. The AVHRR Deep Blue data described in this work are freely available to download  
710 from <https://portal.nccs.nasa.gov/datashare/AVHRRDeepBlue/>. Data hosting resources were

711 provided by the NASA High-End Computing (HEC) Program through the NASA Center for  
712 Climate Simulation (NCCS) at Goddard Space Flight Center. NOAA L1B GAC data were  
713 obtained from <https://www.class.ncdc.noaa.gov>. MERRA2 data were obtained from NASA's  
714 Goddard Earth Sciences Data and Information Services Center (<https://disc.gsfc.nasa.gov>). We  
715 would also like to express our gratitude to AERONET site PIs (<https://aeronet.gsfc.nasa.gov>) in  
716 establishing and maintaining the long-term stations used in this investigation. The authors thank  
717 three anonymous reviewers for their helpful suggestions.

940  
 941 Table 1. AVHRR channel names, approximate ranges of peak spectral response, and shorthand  
 942 for central wavelengths indicated in this study. Note channel 3A is only present on the  
 943 AVHRR/3 sensors (NOAA15 onwards).

944

Number	Range of peak spectral response ( $\mu\text{m}$ )	Shorthand
1	0.58-0.68	630 nm
2	0.72-1.0	850 nm
3a	1.58-1.64	1.6 $\mu\text{m}$
3b	3.55-3.93	3.7 $\mu\text{m}$
4	10.30-11.30	11 $\mu\text{m}$
5	11.50-12.50	12 $\mu\text{m}$

945

946

947

948 Table 2. Aerosol optical model, AOD ranges, FMF values, size distribution parameters,  
 949 refractive indices, and references for the AVHRR application of SOAR. For each model fine  
 950 mode parameters are on the first line and coarse the second.

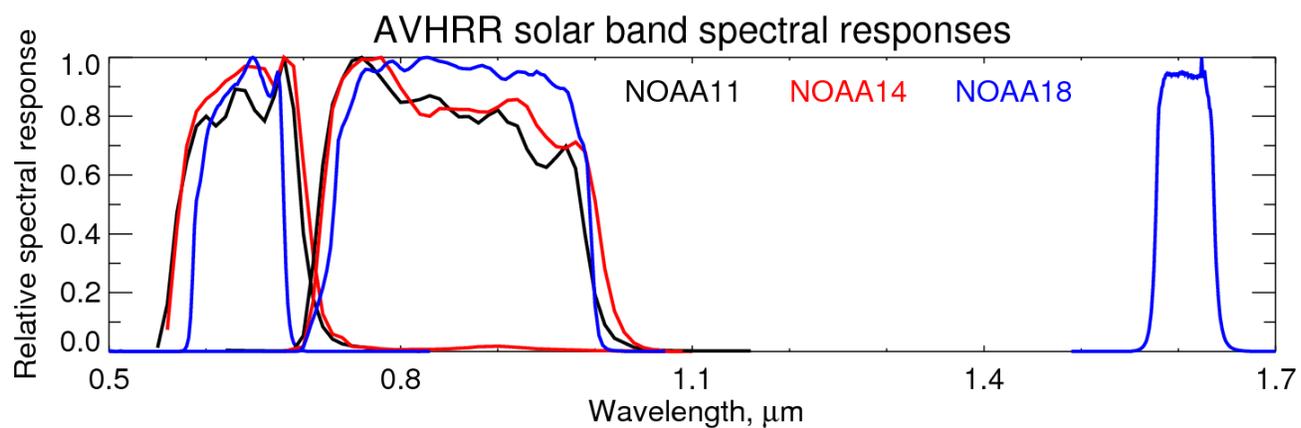

Model	Referenc e	FM F	AOD range	Modal radius, $\mu\text{m}$	Spread	Refractive index (550, 630, 840 nm)
